

Introduction to Program Analysis

CSE552 Program Analysis — Lecture 1

Jaemin Hong

Instructor Information

- ▶ Name: Jaemin Hong
- ▶ Email: `jaemin.hong@unist.ac.kr`
- ▶ Website: <https://hjaem.info/>
- ▶ Research Areas: Programming Languages, Static Analysis, Program Transformation
- ▶ Office: Room 710-1, Building 106
- ▶ Office Hours: Wednesday 10:00–11:00 AM (or by appointment)

Course Information

- ▶ Lecture slides will be provided
- ▶ Textbook: “Static Program Analysis” by Anders Møller and Michael I. Schwartzbach
 - ▶ <https://cs.au.dk/~amoeller/spa/>
- ▶ Reference: “Introduction to Static Analysis: An Abstract Interpretation Perspective” by Xavier Rival and Kwangkeun Yi

Grading

- ▶ Midterm Exam: 25%
- ▶ Final Exam: 25%
- ▶ Assignments: 20%
 - ▶ 4 programming assignments (5% each)
- ▶ Presentations: 30%
 - ▶ Term project and end-of-term presentation
 - ▶ Define your own software problem and solve it by designing and implementing a static analysis
 - ▶ Details will be provided later

Motivation 1: Program Transformation

- ▶ Compiler optimization significantly affects software performance
- ▶ GCC -O0 vs -O3: 1.2x–15x speedup¹
- ▶ How can we optimize programs automatically?

¹Impact of GCC optimization levels in energy consumption during C/C++ program execution (Branco and Henriques, 2015)

Example: Loop-Invariant Code Motion

Original:

```
for (i = 0; i < n; i++) {  
    y = x * x;  
    print(y);  
    *p += 1;  
}
```

Optimized:

```
y = x * x;  
for (i = 0; i < n; i++) {  
    print(y);  
    *p += 1;  
}
```

Does $x * x$ evaluate to the same value in every iteration? If so, we can move it outside the loop

Program Transformation: Key Insight

- ▶ Semantics-preserving transformation for optimization or refactoring requires understanding program behavior
- ▶ We need to know what the program does
- ▶ This is where program analysis comes in

Motivation 2: Bug Finding

Software bugs can lead to:

- ▶ Significant financial losses
- ▶ Security breaches
- ▶ Loss of life

We need automated techniques to find bugs before they cause damage

Historical Bug Example: Ariane 5

- ▶ Ariane 5 rocket failure (1996)
- ▶ Bug type: Integer overflow
- ▶ Impact: Loss of more than \$370 million²

²The Ariane 5 software failure (Dowson, 1997)

Historical Bug Example: Therac-25

- ▶ Therac-25 radiation therapy machine (1985–1987)
- ▶ Bug type: Data race
- ▶ Impact: At least 6 accidents, resulting in death or serious injury³

³An investigation of the Therac-25 accidents (Leveson and Turner, 1992)

Historical Bug Example: Heartbleed

- ▶ Heartbleed bug (2014)
- ▶ Bug type: Buffer overflow
- ▶ Impact: Estimated cost of \$500 million⁴

⁴Ten most expensive bugs in history (part 2) (Sixsentix, 2024)

Bug Finding Example

- ▶ Can this divisor expression evaluate to zero? If so, we have a division by zero error
- ▶ This is a question that program analysis can answer

Motivation 3: Program Comprehension

- ▶ Modern development process heavily utilizes IDEs or editor plugins
- ▶ Example: “mouse hover” to show the type of an expression

```
# Add grades
alice.add_grade(95.5)
alice.add_grade(87.0)
alice.add_grade(92.5)

bob.add_grade(78.0)
bob.add_grade(85.5)

(variable) alice_avg: float | None
alice_avg = alice.get_average()
bob_avg = bob.get_average()

print(f"{alice.name}'s average: {alice_avg}")
print(f"{alice.name}'s letter grade: {alice.get_letter_grade()}")

# Calculate class statistics
students = [alice, bob]
stats = calculate_class_statistics(students)
print(f"Class statistics: {stats}")
```

```
# Add grades
alice.add_grade(95.5)
alice.add_grade(87.0)
alice.add_grade(92.5)

bob.add_grade(78.0)
bob.add_grade(85.5)

# Get averages
alice_avg = alice.get_average()
bob_avg = bob.get_average()

print(f"{alice.name}'s average: {alice_avg}")
print(f"{alice.name}'s letter grade: {alice.get_letter_grade()}")

# Calculate class statistics
(variable) stats: dict[str, float] | dict[str, Any]
stats = calculate_class_statistics(students)
print(f"Class statistics: {stats}")
```

Program Analysis

A collection of techniques to automatically figure out the properties of given programs

Essential for:

- ▶ Program transformation
- ▶ Bug finding
- ▶ Program comprehension

Static vs Dynamic Analysis

- ▶ Static: without executing the program
- ▶ Dynamic: by executing the program

Focus of This Course: Static Analysis

- ▶ We will focus on static analysis techniques
- ▶ Why static analysis?

Static Analysis: Advantages

- ▶ Ensures termination
 - ▶ Execution may not terminate
- ▶ Does not require concrete inputs
 - ▶ Execution requires concrete inputs
- ▶ Can deal with partial programs
 - ▶ Execution requires complete programs

Static Analysis: Limitations

- ▶ Cannot be both sound and complete for non-trivial properties
- ▶ We must choose: soundness or completeness?

Soundness and Completeness

Soundness: If the analysis says a certain behavior is impossible, then it is indeed impossible

- ▶ Overapproximates possible behaviors
- ▶ No false negatives

Completeness: If the analysis says a certain behavior is possible, then it is indeed possible

- ▶ Underapproximates possible behaviors
- ▶ No false positives

Example: Soundness vs Completeness

```
if (...) {  
    x = 1;  
} else {  
    x = 2;  
}  
return x;
```

Sound analysis may say:

- ▶ “x is 1 or 2” ✓
- ▶ “x is a positive integer” ✓
- ▶ “x is any integer” ✓
- ▶ but NOT “x is 1” ✗

Complete analysis may say:

- ▶ “x is 1” ✓
- ▶ “x is 2” ✓
- ▶ “x is 1 or 2” ✓
- ▶ but NOT “x is a positive integer” ✗

The Ideal: Sound and Complete

Ideally, we want a sound AND complete analysis:

- ▶ If it says a behavior is impossible $\Rightarrow$ it is indeed impossible
- ▶ If it says a behavior is possible $\Rightarrow$ it is indeed possible
- ▶ No false negatives AND no false positives

But is this possible?

Rice's Theorem

Rice's Theorem: Any non-trivial property of the behavior of programs in a Turing-complete language is undecidable⁵

⁵Classes of recursively enumerable sets and their decision problems (Rice, 1953)

Rice's Theorem: Example

- ▶ Solving an analysis problem is at least as hard as solving the halting problem, which is undecidable

```
if (...) {  
    f();  
    x = 1;  
} else {  
    x = 2;  
}  
return x;
```

- ▶ x can be 1 only when $f()$ terminates
- ▶ Determining this requires solving the halting problem
- ▶ We must choose either soundness or completeness

Soundness vs Completeness: Which to Choose?

The choice depends on the application

Let's consider two applications:

1. Semantics-preserving transformation
2. Bug finding

For Semantics-Preserving Transformation

```
if (x == 1) { ... } else { ... }
```

- ▶ If a complete analysis says “x is 1”:
 - ▶ Only with this information, we CANNOT remove the else branch
 - ▶ It might miss the case where x is not 1
- ▶ If a sound analysis says “x is 1”:
 - ▶ x can have no other value
 - ▶ We CAN safely remove the else branch

Conclusion: We need sound analysis

For Bug Finding

- ▶ A sound analysis:
 - ▶ Allows proving the absence of bugs
 - ▶ But often suffers from false alarms
- ▶ A complete analysis:
 - ▶ Never produces false alarms
 - ▶ But may miss some bugs
- ▶ Dynamic analyses are complete:
 - ▶ “Program testing can be used to show the presence of bugs, but never to show their absence.”⁶
- ▶ To complement dynamic analyses, people often design sound static analyses

⁶The humble programmer (Dijkstra, 1972)

Designing Sound Analyses: Challenge

- ▶ A sound analysis is easy to implement if soundness is the only goal
 - ▶ An analysis that says “every behavior is possible” is trivially sound
 - ▶ But it is useless
- ▶ To be useful, a sound analysis should be precise as well

Precision

- ▶ An analysis is more precise if the set of computed possible behaviors is smaller
- ▶ Example (from more to less precise):
 - ▶ “x is 1 or 2” (most precise)
 - ▶ “x is a positive integer”
 - ▶ “x is any integer” (least precise)
- ▶ This coincides with the usual use of the term “precision”:
 - ▶ $\text{precision} = \text{true positives} / \text{all positives}$

Goals in Static Analysis Design

Minimal goals:

- ▶ Termination
- ▶ Soundness

Additional goals (to make it useful):

- ▶ Efficiency
- ▶ Precision

Trade-off: Often exists between efficiency and precision

Course Objectives

- ▶ Understand existing static analysis techniques
 - ▶ Type analysis, interval analysis, Andersen-style pointer analysis, etc.
- ▶ Understand frameworks for designing new static analyses
 - ▶ Unification, monotone framework, cubic solver
- ▶ Reason about the soundness of static analyses
 - ▶ Abstract interpretation

Learning in the LLM Era

Quote from Chris Lattner (creator of LLVM, Clang, Swift, MLIR):⁷

“The scarce skills become choosing the right abstractions, defining meaningful problems, and designing systems that humans and AI can evolve together.”

“Engineers should clarify intent with rigor, validate outcomes with tests, and improve their design.”

⁷<https://www.modular.com/blog/the-claude-c-compiler-what-it-reveals-about-the-future-of-software>

LLMs and This Course

- ▶ LLMs are already good at implementing PL techniques, including static analysis
- ▶ **You are allowed and encouraged to use LLMs** for assignments and project
- ▶ Focus on:
 - ▶ Understanding important ideas in static analysis
 - ▶ Designing high-level structures
 - ▶ Finding effective ways to manage LLMs
 - ▶ Validating the results of LLMs

Summary

- ▶ Program analysis automatically figures out program properties
- ▶ Static analysis (without execution) vs Dynamic analysis (with execution)
- ▶ Static analysis advantages: termination, no inputs needed, partial programs
- ▶ Static analysis limitations: cannot be both sound and complete (Rice's theorem)
- ▶ We focus on sound analyses with high precision
